Imagine a simple game world where the player controls a knight in shining armor, armed with a sword. The knight can move around the environment and use the sword to attack various objects. Some objects can be pushed and repositioned, while others can be interacted with in different ways.

Create classes **Knight**, **Goblin**, **WoodenBox**, **Rock**, **Chest** with appropriate fields and methods, and make sure it has good encapsulation:

- Knight should be able to attack Goblins (they will take damage) and WoodenBoxes (they will break immediately).
- Knight should be able to push WoodenBox, Rock and Chest.
- Knight should be able to interact with Chest to open it.

Use **Abstract Classes** and **Interfaces** to connect everything together. Create a **Game** class with the main method to test everything.

P.S.: You can skip implementation of some methods like `destroy()` or `die()` and just write `TODO` or console output there.
